Ensayo del tema:

“Sings and symptoms”

WHAT IS A SYMPTOM?

The symptoms can only be described by the person who feels them. For example if you have pain nobody knows unless you tell them it is the same with dizziness, headache, lightheadedness, fatigue, vision disorders, ringing in the ears and a host of other feelings. Anyone other than you in your body will only know about these experiences if you describe them.

WHAT IS A SIGN?

Vital signs show how well your body is working. I usually know in the doctor's office, often as part of a checkup or during an emergency medical visit. These include your respiratory rate, heart rate (pulse), temperature, and blood pressure. Vital signs may also include other measures, such as pulse oximetry (how much oxygen is in the blood)

▼ PULSO.

▼ RESPIRACIÓN.

▼ TEMPERATURA CORPORAL.

▼ TENSIÓN ARTERIAL.

WHY PEOPLE USUALLY CONFUSE SIGNS AND SYMPTOMS?

Well, an example here is when they look at a person scratching their arm, people confuse it with a symptom when observing, since this refers to a sign that is in charge of observing, measuring and monitoring and evaluating their level of physical functioning.

the direction here would be that a sign is the objective manifestations, clinically reliable, and observed in the medical examination of the patient, a difference of the symptoms, which are subjective elements, specific perceived signals by the patient, as, for example, in this case it would be itchy arm as it can be referred to as allergic reactions other examples of symptoms would be headache, cough, and bone pain.
